

AURORA GATEWAY - SERVICE LIMITS AND QUOTAS

This sheet states the per-tenant quotas enforced by the Aurora Gateway. Runtime behaviour such as the listen port or the session ceiling is described in the operator handbook instead; the two documents never restate each other's numbers.

Throughput

Each tenant is entitled to a sustained throughput of 200 requests per second. Bursts are permitted up to 400 requests per second, after which the gateway throttles rather than rejects. A burst allowance lets a cold client catch up without letting one tenant consume the whole service.

Payloads

The largest request body a tenant may send is 4 MB. The largest response the gateway will produce for one request is 8 MB. Both ceilings are enforced before the request reaches the session pool, so an oversized upload costs a tenant nothing but the bytes it already sent.

Storage and retention

A tenant may store at most 5,000 documents. Documents are retained for 90 days from the moment they are ingested; after that they are purged and the quota is released. A document that is deleted by its owner is released immediately and does not wait for the retention window to close.

Enforcement

A request that exceeds its quota is answered with HTTP 429 and a Retry-After header naming the second at which the quota resets. Quotas reset at 00:00 UTC. There is no burst credit carried across a quota reset: a tenant that has used its full throughput in the final second of a minute starts the next minute with the full allowance and nothing more.
